Symbiosis, Endosymbiosis, Symbiosis at the molecular level
Inteins

For Friday: Alphafold is hosted on a google server. To use it, you need to have a working Google account.

On Friday you will need your **Google username and password.**

Heinrich Anton de Bary

“Die Erscheinung der Symbiose” (Strausbourg, 1879)

- Parasitism/Antagonism
- Commensalism
- Mutualism
- Lichenism/Symbiogenesis

Beatrix Potter

Was not allowed to present her 1897 paper on lichen symbionts to the Royal Academy of Sciences due to her gender (an apology was issued on the 100 year anniversary of the event)

Symbiosis (from Wikipedia)

Symbiosis (from [Greek](#) συμβίωσις "living together", from σύν "together" and βίωσις "living") is any type of a close and long-term [biological interaction](#) between two different biological organisms, **be it [mutualistic](#), [commensalistic](#), or [parasitic](#)**. The organisms, each termed a **symbiont**, may be of the same or of different [species](#). In 1879, [Heinrich Anton de Bary](#) defined it as "the living together of unlike organisms".

The term was subject to a century-long debate about whether it should specifically denote mutualism, as in [lichens](#); biologists have now abandoned that restriction.

According to this definition,

all parasites that live closely with their host are symbionts!

Wikipedia is not infallible, but among most scientists this is accepted – but apparently not by all.

What might be the reason for the popularity of the more encompassing definition?

Examples of mutualistic symbiosis

- (Endo)symbiotic [nitrogen-fixing](#) bacteria in Alder (*Frankia*) and related tree, in Leguminosae (*Rhizobium*), in Gunera (*Nostoc*)
- Lichen: symbioses between fungi and eukaryotic algae or cyanobacteria
- Mycorrhiza in plants: fungi take over the role of root hairs
- Microbiota in the gut of animals (digestions of cellulose and other compounds, vitamin biosynthesis, production of group specific smell, synthesis of essential amino acids (especially in sap eating insects))
- Microorganisms in the rhizosphere of plants (provide nutrients and water).
?Communication between neighboring plants (the wood wide web)?

Aid from neighboring trees, reserves and effective wound healing, or two stems from the same tree?

Tree stump on Vashon island (near Seattle, Washington). The stump's surface has been completely overgrown by new bark.

Example of the [wood wide web](#)?

See [here](#) for a critical assessment.

Mitochondria and Plastids

- Have their own circular chromosome.
- Surrounded by two membranes – the inner membrane is similar to bacterial membranes.
- Have their own ribosomes.
- Many of the enzymes functioning in these organelles are very similar to their bacterial homologs (ATP synthase, ribosomal proteins).
- Today there is no doubt that plastids and mitochondria evolved from bacteria that lived as endosymbionts inside a host cell (related to Archaea).

Lynn Margulis and the Serial Endosymbiotic Theory

In 1967, [Lynn Margulis](#) revived the old but largely ignored theory of symbiogenesis. She proposed three mergers. The first merger is poorly supported and now not generally believed.

Molecular phylogenies provide overwhelming support for the bacterial origin of mitochondria and plastids.

Conservation of intron and intein insertion sites: Implications for life histories of parasitic genetic elements.
BMC Evolutionary Biology 2009, 9:303 doi:10.1186/1471-2148-9-303 (Highly Accessed)

In case of inteins the co-evolution of genes results in

- **Mutualism** between splicing and homing endonuclease domain

- **Commensalism** between host protein and intein without HE domain

- **Parasitism** between host protein and intein with HE

Encoding

Extein = Host Protein

Intein Splicing Domain

Homing Endonuclease (HE) domain

Structure from Moure et al. (2002)
Nat.Struct.Biol. 9: 764-770

Comparison of intein and hedgehog protein structures. The structures of the *Sce* VMA, *Mxe* GyrA, and the autoprocessing domain of the hedgehog protein from *Drosophila melanogaster* have been determined by X-ray crystallography. The pdb-files were retrieved from the Protein Data Bank and processed using the Swiss-PdbViewer. The *orange arrows* and *red helices* indicate β -sheets and α -helices. The amino-terminal β -sheets are colored in *green*, and the carboxy-terminal β -sheets are shown as *blue arrows*. The endonuclease domain present in *Sce* VMA (*top panel, right*) forms a domain clearly distinct from the self-splicing domain (*top panel, left*). The part of the *Sce* VMA structure that is not part of the endonuclease domain, but partakes in DNA binding, is depicted in *light blue*.

Inteins have a high fitness cost for the host organism.

How can inteins with functional homing endonuclease survive on the long run?

- Homing cycle
- Coexistence of the three forms (predator prey with three partners, in an intransitive fitness relationship)
- Diverse environment with regions that select for the intein, and those that don't

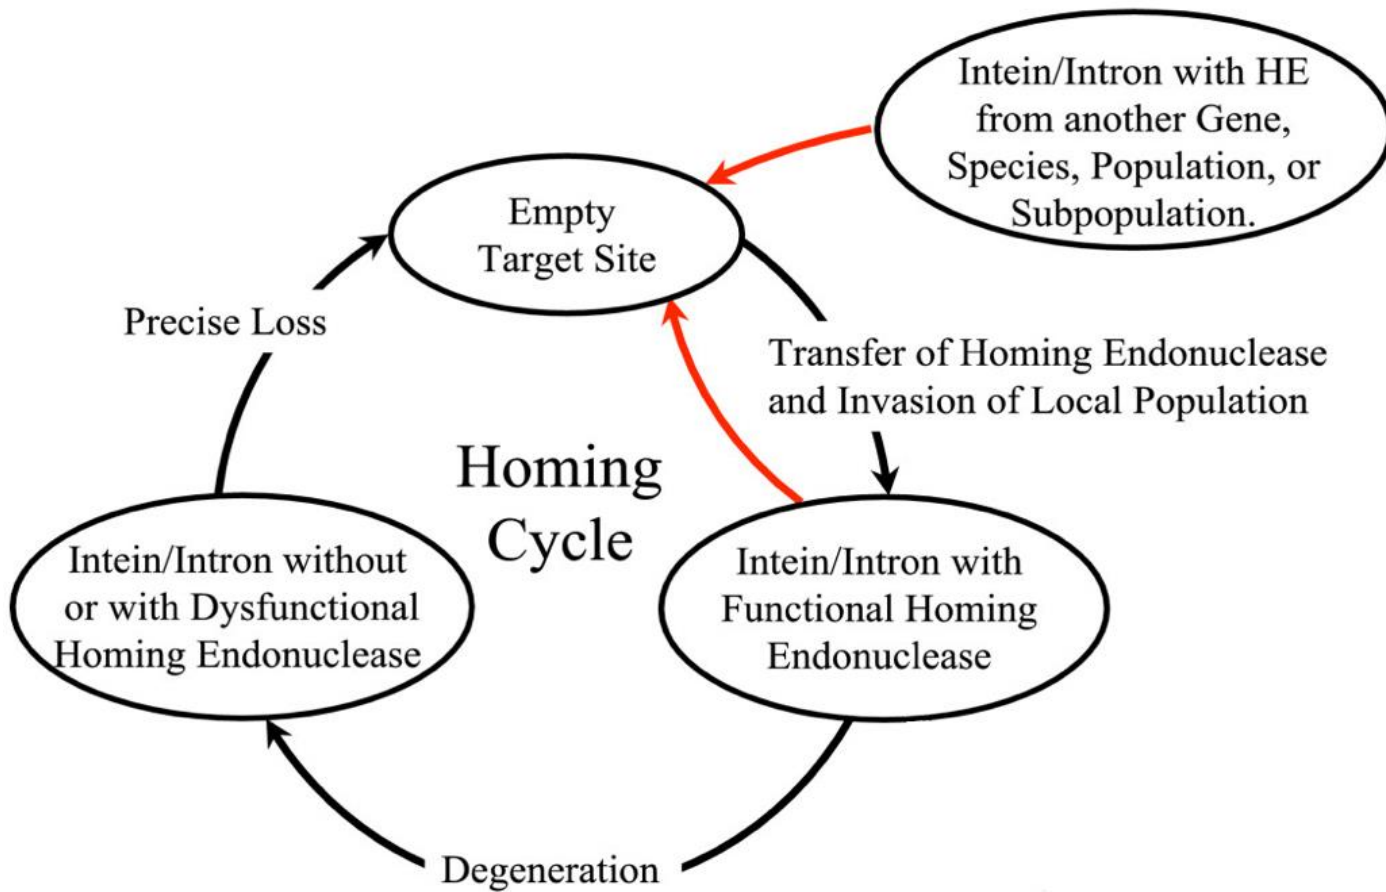

Three models for long term intein persistence

1)the homing cycle

The Homing Cycle

Homing Cycle of an Intein or Group 1 Intron

Local population with **only empty target sites**

Invasion of target sites

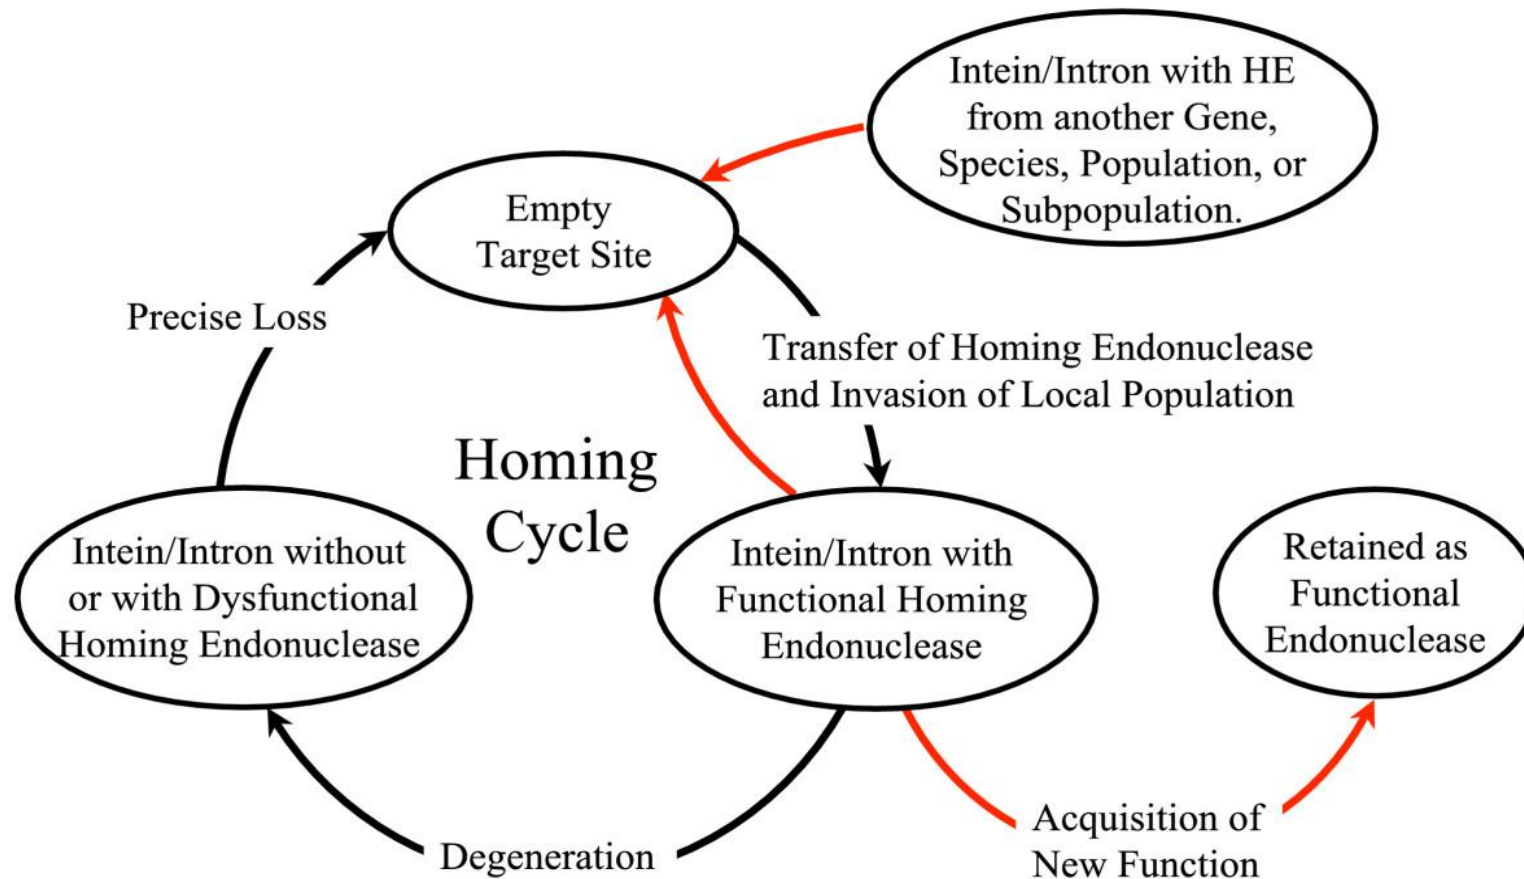

All sites are occupied with **full intein**

Degeneration of Homing Endonuclease

Only Mini-Inteins are present

Loss – Difficult in case of inteins.
If invasion was complete,
no intein free template nucleotide
sequence is available as template

Each phase (invasion, degeneration, loss) goes to completion, before the next begins.

Homing cycle of a parasitic genetic element (modified from [3, 13]). Recent findings suggest that due to complex population structure the cycle might not operate in synchrony in different subpopulations. The red arrows indicate the trajectory of the functioning HE and the black arrows the fate of the host gene. The precise loss can occur through recombination with an intein or intron free allele, or, in case of introns, through recombination with a reverse transcript of the spliced mRNA [39, 40].

<http://staff.wvu.edu/~larserik/applmath/chap9en/part7.html>

https://en.wikipedia.org/wiki/Van_der_Pol_oscillator

Fixed points, like A , B , and C , satisfy $dfx_1/dt = dfx_2/dt = 0$, and correspond to steady states or equilibria of the system. The **closed orbits**, like D correspond to periodic solutions.

Three models for long term intein persistence

- 1) the homing cycle
- 2) Co-existence of the three allele types in a homogeneous population
- 3) Co-existence of the intein with homing endonuclease (P+) and the allele with an empty target site (P-) in a heterogeneous environment

Co-existence in a **heterogenous** population

Arguments in favor for a co-existence in a heterogenous population

1) the intein can have a strong negative effect on organismal fitness

Competition Experiment between Intein + and Intein – strains (otherwise isogenic)

From: Impact of a homing intein on recombination frequency and organismal fitness. Naor et al. [doi: 10.1073/pnas.1606416113](https://doi.org/10.1073/pnas.1606416113)

fitness. Naor et al. [doi: 10.1073/pnas.1606416113](https://doi.org/10.1073/pnas.1606416113)

Co-existence in a heterogenous population

Arguments in favor for a co-existence in a heterogenous population

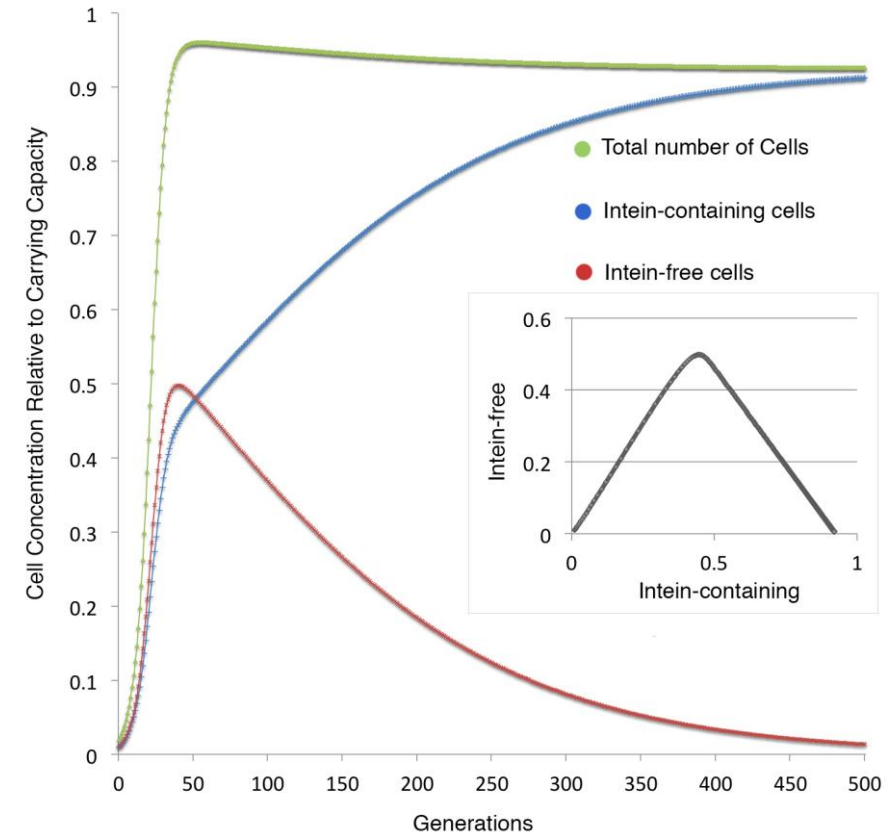

- 1) the intein can have a string negative effect on organismal fitness
- 2) Due to the large fitness cost the intein – alleles dominate during initial phase of the growth curve

On the right is a simple logistic growth curve (with discrete generations) generated with an excel spreadsheet
The simulation starts with .01 **intein +** and .01 **intein -** cell

At the beginning of the growth curve
the **intein -** cells outcompete the **intein +** cells because
the **intein -** cells grow faster

At the end of the growth curve
the **intein -** are converted into **intein +** through HGT and
homing (close to carrying capacity, there is little growth,
the fitness cost does not play a big role

The carrying capacity (available resources) are the same
for both; with **intein +** cells requiring more resources

Intein invasion dynamics in a population with carrying capacity. Number of cells relative to the carrying capacity is plotted for the total number of cells (green line), the intein-containing cells (blue line), and the intein-free cells (red line) over 500 generations. The inset panel shows the concentration of intein-free alleles plotted against the concentration of intein-containing alleles. The simulation assumes that the fitness cost lowers the growth rate as well as the carrying capacity of the intein-containing cells. Parameters: homing efficiency = 0.01; fitness cost = 0.075; carrying capacity 1; growth rate 0.2 per generation; starting concentration 0.01 each for the intein-containing and intein-free cells.

Summary of NetLogo Procedures

Procedure	Description	Value
Movement	Microbes move fixed Move_Distance in a random direction. Movement occurs at intervals of Move_Interval ticks.	Move_Distance = [0.1, 1] (patch-lengths) Move_Interval = [1, 10] (ticks)
Resource Gathering	Microbes advance Replication_Timer in increments of 1, divided by the local cell density.	1 / (count turtles in radius 0.5)
Replication	Microbes divide if their Replication_Timer exceeds Generation_Time. Inein expression results in an 8% fitness cost.	Generation_Time = [100 (Int-), 108 (Int+)] (ticks)
Mating	Microbes co-localized to a set radius fuse according to Mating_Efficiency.	Mating_Efficiency = [1.00E-4 – 2.50E-4]
Homing	Int(-) microbes are converted to Int(+) while mating with an Int(+) microbe based on Homing_Efficiency.	Homing_Efficiency = 0.68
Death	Microbes die at random based on intrinsic Death_Rate, and die probabilistically based on zonal Lethality, at intervals of Dieoff_Frequency.	Death_Rate = 0.001 Dieoff_Frequency = 500 (ticks) Lethality = [0.20, 0.40, 0.60]

Explains what occurs during every tick of each simulation

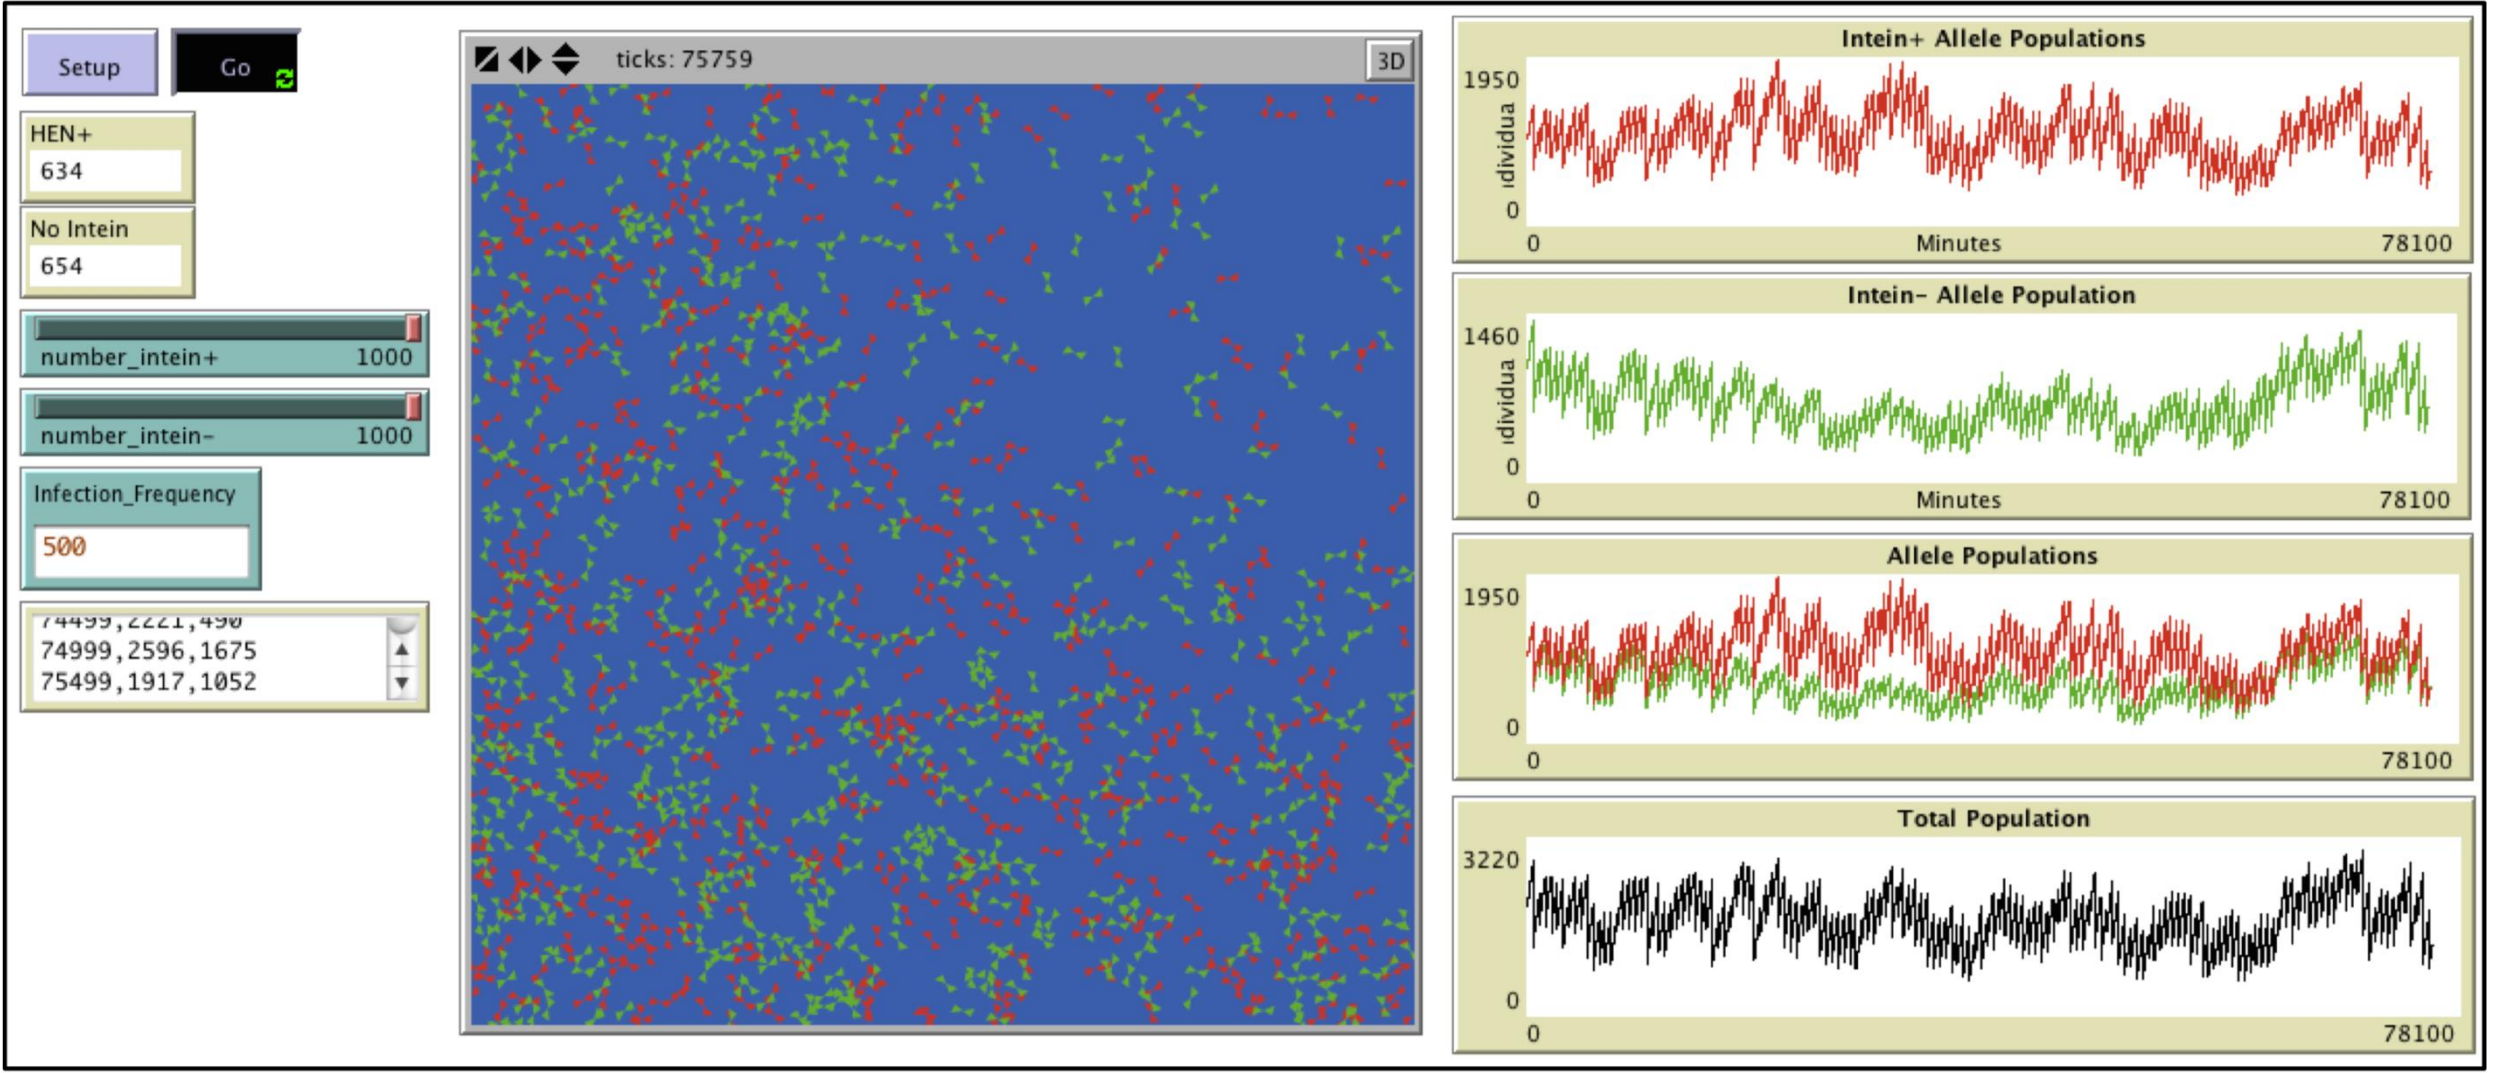

Somewhat wordy in its current form. May not be necessary with inclusion of a “Methods” section

T.B.C. - In current form, doesn't include fringe experiments (e.g. transfer rate between two environments, die-offs in random radii, etc.)

First Netlogo Experiments

Initially, we (i.e., Josh Skydel) explored a single environment into which local extinction events were placed at random

Agent Based Modeling of Intein-containing Populations

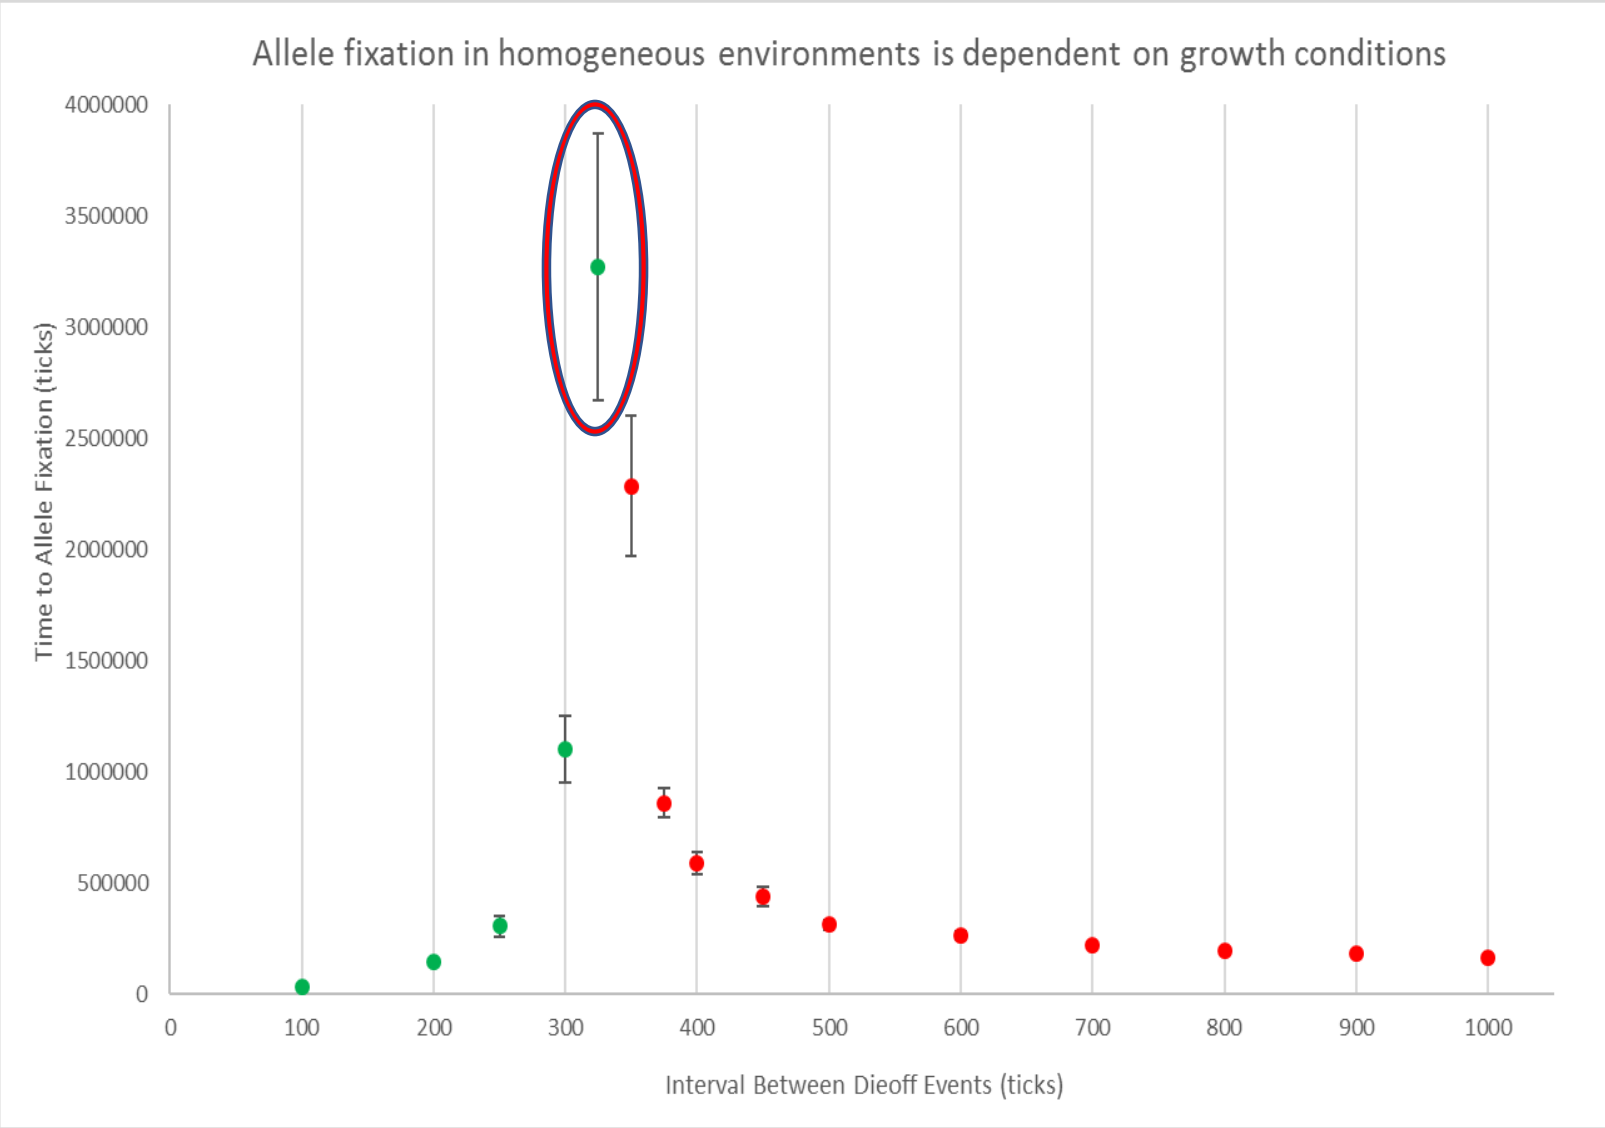

Viral infections create local environments of reduced cell density. Organisms in the modeled space are sensitive to the cell density of their surroundings in respect to their ability to replicate. Viral infections periodically kill all individuals in a randomly located radius. The cell density in that area is gradually restored as organisms migrate into the area; these individuals also gain a replicative “boost” from the lowered cell density in the region.

Sadly, this worked less well than expected
(the PI's wishful thinking failed).

While a set of parameters existed that gave rise to longer term coexistence; however, this "equilibrium" was unstable.

The asymptotically stable solutions had either the intein containing allele, or the intein free allele surviving.

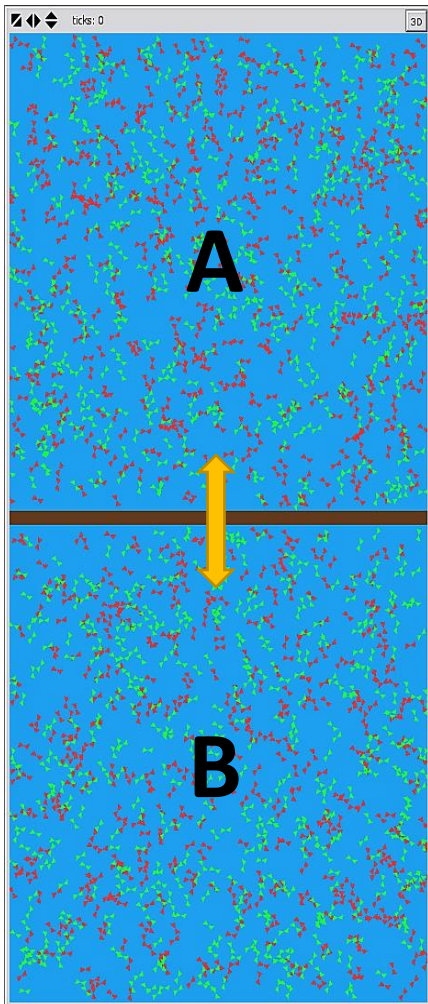

Environment without barrier and random, localized extinction events.

A solution was to have two distinct environments linked by migration between the two environments.

In one environment the *intein plus* alleles are favored, in the other the *intein minus* alleles

Agent-Based Modeling of Microbial Communities

Population held in exponential phase

Population enters stationary phase

- The agent-based modeling platform NetLogo was used to assess the population dynamics of molecular parasites known as inteins
- Simulated microbial agents independently move, acquire resources, replicate, mate, and die
- User-defined parameters influence cellular movement, mating frequency, and community growth state
- The ultimate distribution of inteins was dependent on whether the community spent more time in exponential or stationary phase
- Limited transfer between sub-environments promoted limited allele coexistence

One environment with a gradient in efficiency of local extinction events

Extinction efficiency

Development over time

Close to stationary phase: Inteins transmission continues, increasing the frequency of the invaded allele

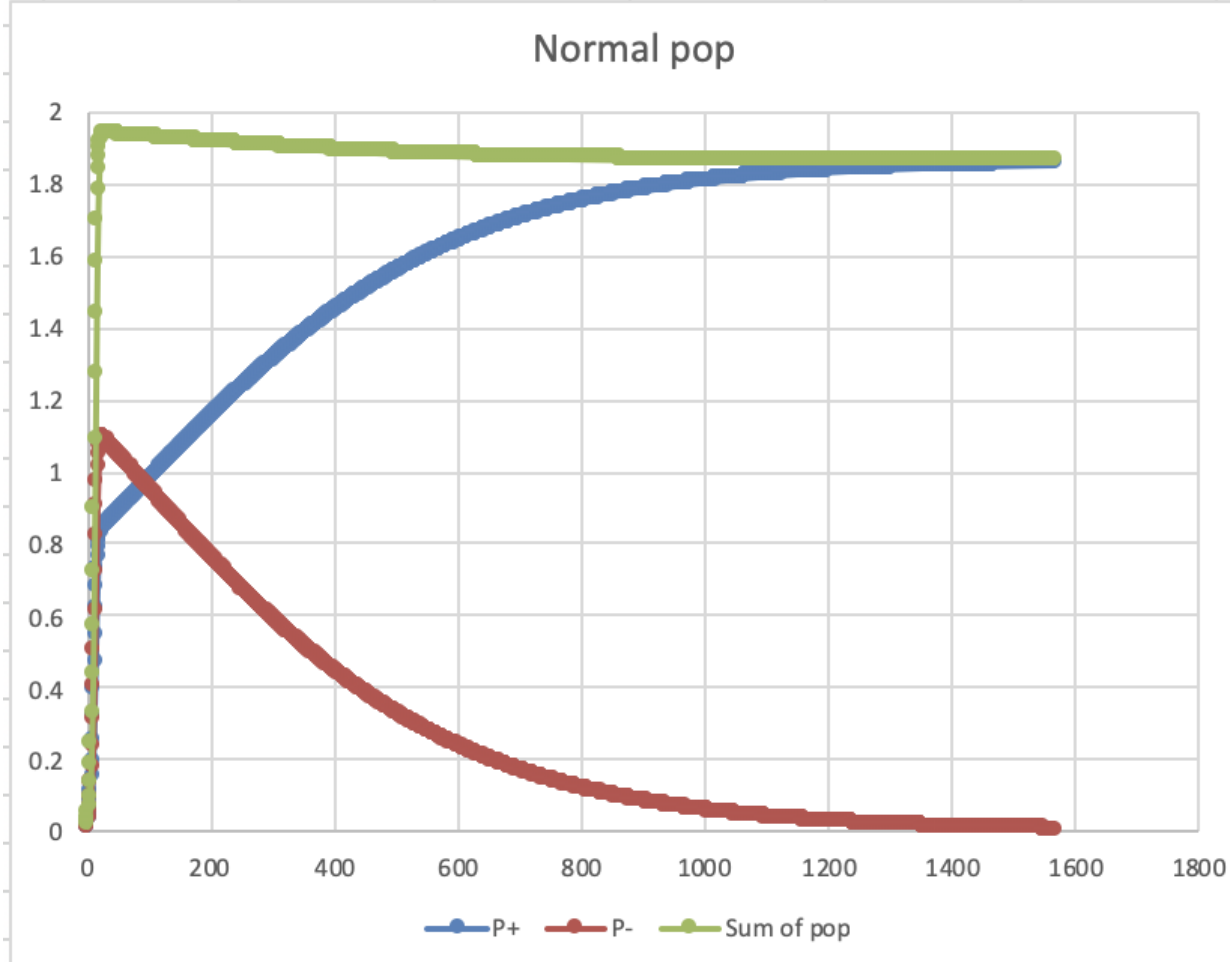

During active growth: Due to fitness cost of the intein, the frequency of the noninvaded allele increases

Convergence to a stable fraction of intein alleles

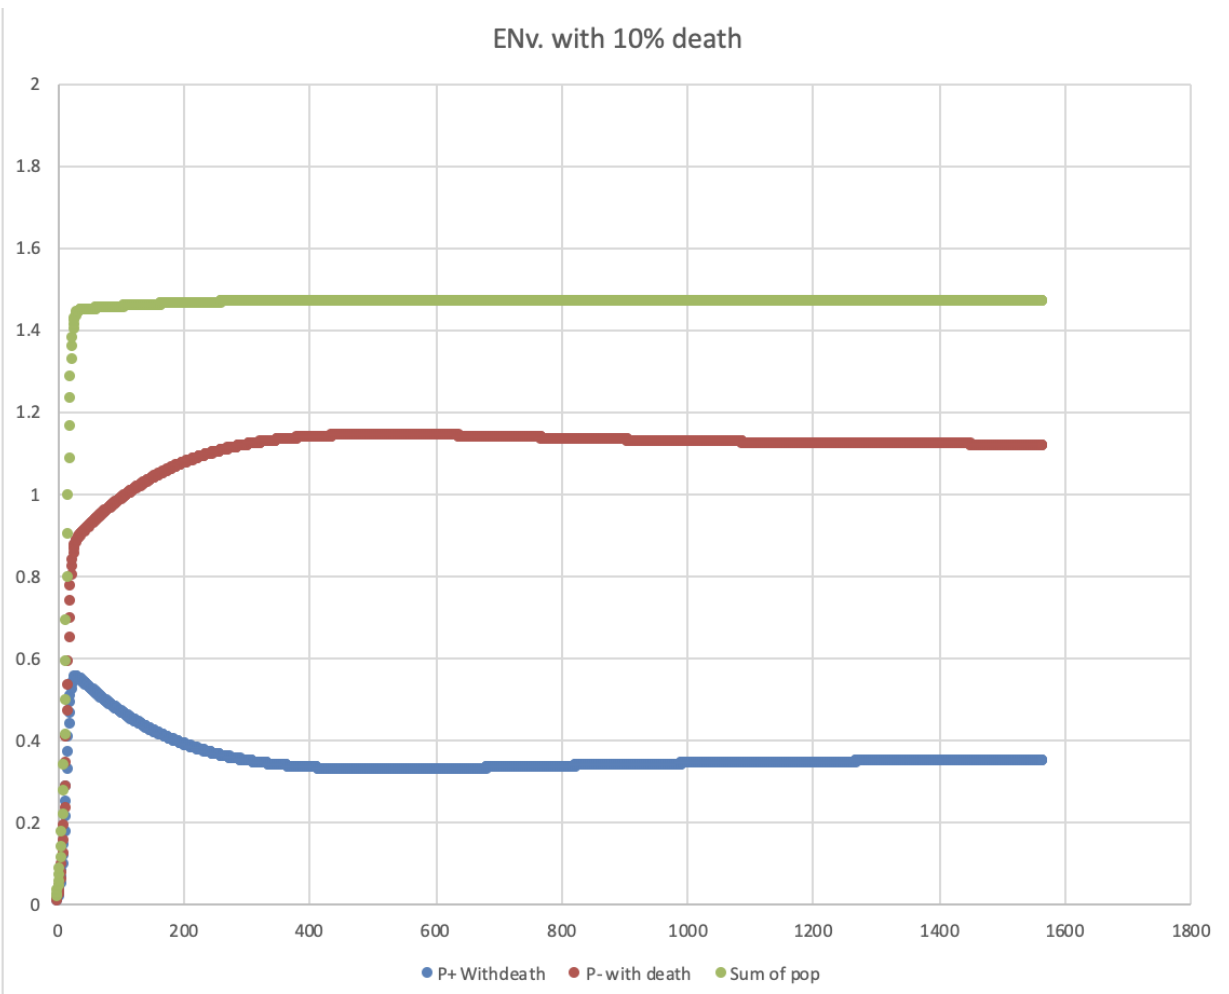

- Starting Int(+) allele fraction = 10% - 90%
- Equilibrium Int(+) fraction determined from final fraction for simulations beginning with equal allele representation
- Int(+) allele was fixed in two simulations when starting fraction was 90%

Using Excel and two populations following a discrete logistic growth
One population has a death rate of 10% per generation; no migration

Rate for successful homing: 0.002; Fitness cost due to intein: 0.075; Growth rate: 0.2; Carrying capacity: 2

Using Excel and two populations following a discrete logistic growth
One population has a **death rate of 10% per generation**
Same as before, but every generation
0.1% moves from one environment to the other

(note each of the environments is homogenous, the P+ and P- are continuous variables)

The trajectories after disturbances plotted as vectors -- 0 (immediately after the disturbance) -> 4 generations later

Co-existence in a **heterogenous** population

Arguments in favor for a co-existence in a heterogenous population

- 1) the intein can have a strong negative effect on organismal fitness
- 2) Due to the large fitness cost, the intein + and intein – alleles dominate during different parts of the growth curve
- 3) Co-existence of the intein with homing endonuclease (P+) and the allele with an empty target site (P-) in a heterogenous environment.

Intein containing and intein free alleles have been isolated from the same populations.
(See Shannon Soucy and Yutian Feng)

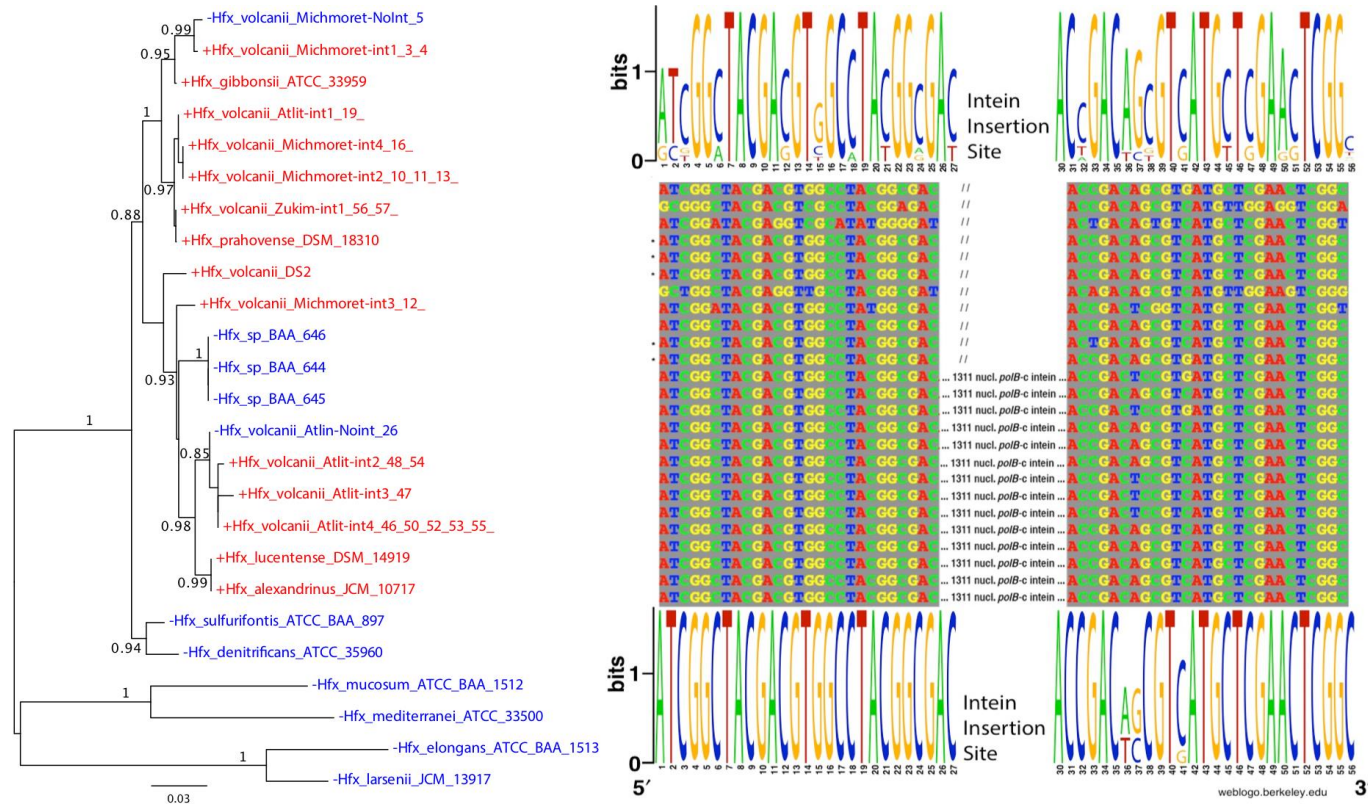

Fig 6. Maximum likelihood phylogeny for *polB* extein sequences (left) and conservation of *polB*-c intein insertion sites (right). Numbers give support values calculated using the approximate Likelihood Ratio Test as implemented in phylml 3.0 (32). Although drawn as a rooted, the tree should be considered unrooted. The finding that sequences **without (blue)** and **with intein (red)** do not always form distinct clans (34) reveals that invasion of the *Haloferax* genus with the *polB*-c intein is an ongoing process. The panel on the right shows a *polB* nucleotide sequence alignment around the intein insertion site c. Web logos (33) give the site conservation for intein minus (top) and intein plus sequences (bottom). The five intein minus sequences that group within the cluster of intein plus sequences are marked with an asterisk. The intein minus sequences show greater nucleotide diversity surrounding the intein insertion site, mainly in synonymous positions -- only two positions at the 5' and close to the 3' end of the alignment represent non-synonymous changes. Homing endonuclease site specificity was shown to tolerate substitutions that result in non-synonymous changes (35), suggesting that none of the depicted *Haloferax* sequences may be immune to intein invasion.

Frequency of reads mapped to *Natronomonas moolapensis* rir1g

Reads mapped to *Natronomonas moolapensis* rir1g with intein removed Lake Meyghan

Reads mapped to *Natronomonas moolapensis* rir1g with intein Lake Meyghan

- Metagenomic reads from Lake Meyghan* mapped back to reference sequences with and without the intein.
- Intein was artificially removed, to intact insertion site.
- Red lines indicate intein boundaries, sharp decrease in coverage when intein removed.

Do inteins have a function beneficial to the organisms?

Infinite Regress

After a lecture on the structure of the solar system, the cosmologist William James was accosted by a little old lady.

"Your theory that the sun is the centre of the solar system, and the earth is a ball which rotates around it has a very convincing ring to it, Mr. James, but it's wrong. I've got a better theory," said the little old lady.

"And what is that, madam?" inquired James politely.

"That we live on a crust of earth which is on the back of a giant turtle."

Not wishing to demolish this absurd little theory by bringing to bear the masses of scientific evidence he had at his command, James decided to gently dissuade his opponent by making her see some of the inadequacies of her position.

"If your theory is correct, madam," he asked, **"what does this turtle stand on?"**

"You're a very clever man, Mr. James, and that's a very good question," replied the little old lady, "but I have an answer to it. And it's this: **The first turtle stands on the back of a second, far larger, turtle, who stands directly under him.**"

"But what does this second turtle stand on?" persisted James patiently.

To this, the little old lady crowed triumphantly,

"It's no use, Mr. James—it's turtles all the way down."
